Epidemic models

Epidemic models attempt to capture the dynamics in the spreading of a disease (or idea, computer virus, product adoption).

Central questions they try to answer are:

- How do contagions spread in populations?
- Will a disease become an epidemic?
- Who are the best people to vaccinate?
- Will a given YouTube video go viral?
- What individuals should we market to for maximizing product penetration?

Full mixing assumption

In classic epidemiology, it is assumed that every individual has an equal chance of coming into contact with every other individual in the population

イロト イポト イヨト イヨト

The SI model The SIR model The SIS model

Full mixing in classic epidemiological models

Full mixing assumption

In classic epidemiology, it is assumed that every individual has an equal chance of coming into contact with every other individual in the population

Dropping this assumption by making use of an underlying contact network leads to the more realistic models over networks (second half of the lecture)!

イロト イポト イヨト イヨト

The SI model The SIR model The SIS model

The SI model (fully mixing susceptible – infected) Notation (following [Newman, 2010])

- Let S(t) be the number of individuals who are susceptible to sickness at time t
- Let X(t) be the number of individuals who are infected at time t¹
- Total population size is n
- Contact with infected individuals causes a susceptible person to become infected
- An infected never recovers and stays infected and infectious to others

¹Well, really *S* and *X* are random variables and we want to capture number of infected and susceptible *in expectation*.

Argimiro Arratia & Ramon Ferrer-i-Cancho Epidemic models over networks

The SI model The SIR model The SIS model

The SI model

In the SI model, individuals can be in one of two states:

- susceptible (S), or
- infective (I)

イロト イポト イヨト イヨト

The parameters of the SI model are

 β infection rate: probability of contagion after contact per unit time

The SI model The SIR model The SIS model

The SI model

Dynamics

$$\frac{dX}{dt} = \beta \frac{SX}{n}$$
 and $\frac{dS}{dt} = -\beta \frac{SX}{n}$

where

- S/n is the probability of meeting a susceptible person at random per unit time
- XS/n is the average number of susceptible people that infected nodes meet per unit time
- βXS/n is the average number of susceptible people that become infected from all infecteds per unit time

The SI model The SIR model The SIS model

The SI model

Logistic growth equation and curve

Define s = S/n and x = X/n, since S + X = n or equivalently s + x = 1, we get:

$$\frac{dx}{dt} = \beta(1-x)x$$

The solution to the differential equation (known as the "*logistic* growth equation") leads to the *logistic* growth curve

$$x(t) = \frac{x_0 e^{\beta t}}{1 - x_0 + x_0 e^{\beta t}}$$

イロト イヨト イヨト イヨト

where $x(0) = x_0$

The SI model The SIR model The SIS model

The SIR model

Allowing *recovery* and *immunity*

In the SIR model, individuals can be in one of two states:

- susceptible (S), or
- infective (I),or
- recovered (R)

・ロト ・回ト ・ヨト ・ヨト

The parameters of the SIR model are

- β infection rate: probability of contagion after contact per unit time
- γ recovery rate: probability of recovery from infection per unit time

The SI model The SIR model The SIS model

The SIR model

Dynamics

$$\frac{ds}{dt} = -\beta sx \qquad \qquad \frac{dx}{dt} = \beta sx - \gamma x \qquad \qquad \frac{dr}{dt} = \gamma x$$

The solution to this system (with s + x + r = 1) is not analytically tractable, but solutions look like the following:

The SI model The SIR model The SIS model

The SIR model I

A threshold phenomenon

Now we are interested in considering the *fraction of the population that will get sick* (i.e. size of the epidemic), basically captured by r(t) as $t \to \infty$

Substituting $dt = \frac{dr}{\gamma \times}$ from the third equation into $ds = -\beta sxdt$ and solving for s (assuming $r_0 = 0$), we obtain that

$$s(t) = s_0 e^{-\frac{\beta}{\gamma}r}$$

and so

$$\frac{dr}{dt} = \gamma (1 - r - s_0 e^{-\frac{\beta}{\gamma}r})$$

イロト イヨト イヨト イヨト

The SI model The SIR model The SIS model

The SIR model II

A threshold phenomenon

As $t \to \infty$, we get that r(t) stabilizes and so $\frac{dr}{dt} = 0$, thus:

$$r = 1 - s_0 e^{-\frac{\beta}{\gamma}r}$$

Assume that $s_0 \approx 1$, since typically we start with a small nr. of infected individuals and we are considering large populations, and so $r = 1 - e^{-\frac{\beta}{\gamma}r}$

The SI model The SIR model The SIS model

The SIR model

The basic reproduction number R_0

Basic reproduction number R_0

 R_0 is the average number of additional people that a newly infected person passes the disease onto before they recover².

- R₀ > 1 means each infected person infects more than 1 person and hence the epidemic grows exponentially (at least at the early stages)
- $R_0 < 1$ makes the epidemic shrink
- R₀ = 1 marks the *epidemic threshold* between the growing and shrinking regime

In the SIR model, $R_0 = \frac{\beta}{\gamma}$

²It is defined for the early stages of the epidemic and so one can assume that most people are in the susceptible state. $< \square \lor < \square \lor < \square \lor < ⊇ \lor < ≡ \lor < ≡ \lor < = \lor < □ \lor < □ \lor < □ \lor < = ``$

Solution

$$x(t) = x_0 \frac{(\beta \langle k \rangle - \gamma) e^{(\beta \langle k \rangle - \gamma)t}}{\beta \langle k \rangle - \gamma + \beta \langle k \rangle x_0 e^{(\beta \langle k \rangle - \gamma)t}}$$

Observations

- Same behavior as in the non-networked model
- Epidemic threshold at $\beta \langle k \rangle \gamma = 1$
 - Equivalent to $\frac{\beta}{\gamma} \leq \frac{1}{\langle k \rangle}$, same as SIR

イロン 不同 とくほど 不同 とう

A general network model for SIS [Chakrabarti et al., 2008]

Now we need to consider that infection can be through existing connections

- A is the adjacency matrix of the underlying contact network, and A_{ij} is the entry corresponding to the potential edge between nodes i and j
- Assume A is symmetric (contagion goes in both ways) and has dimension n × n (n is the population size)
- s_i(t) is the probability of node i being susceptible to disease at time t
- \blacktriangleright $x_i(t)$ is the probability of node *i* being infected at time *t*

Homogeneous models A general network model for SIS Scale-free network model for SIS

イロト イポト イヨト イヨト

Model dynamics I

From [Chakrabarti et al., 2008]

"During each time interval Δt , an infected node *i* tries to infect its neighbors with probability β . At the same time, *i* may be cured with probability γ ."

イロト イポト イヨト イヨト

Model dynamics II

Notation

- Let $x_i(t)$ be the probability that node *i* is infected at time *t*
- Let ζ_i(t) be the probability that a node i will not receive infections from its neighbors in the next time step

$$\begin{aligned} \zeta_i(t) &= \prod_{j:i-j}^{j \text{ fails to pass infection}} \underbrace{\chi_j(t-1)(1-\beta)}_{j:i-j} + \underbrace{(1-x_j(t-1))}_{j:i-j} \\ &= \prod_{j:i-j}^{j:i-j} 1 - x_j(t-1)\beta \end{aligned}$$

イロト イヨト イヨト イヨト

Model dynamics III

Then, the probability that a node *i* is uninfected is:

$$1-x_i(t) = \overbrace{\zeta_i(t)}^{\text{neighbors fail to infect}} (\overbrace{(1-x_i(t-1))}^{\text{node is healthy}} + \overbrace{\gamma x_i(t-1)}^{\text{node is infected and curves}})$$

Finally, the fraction of infecteds is computed as:

$$x(t) = \sum_{i} x_i(t)$$

イロト イヨト イヨト イヨト

Threshold phenomenon I

Theorem

The epidemic threshold of the SIS model over arbitrary networks is $\frac{1}{\lambda_1}$, where λ_1 is the largest eigenvalue of the underlying contact network, that is:

• If
$$\frac{\beta}{\gamma} > \frac{1}{\lambda_1}$$
 then epidemic occurs

• If
$$\frac{\beta}{\gamma} < \frac{1}{\lambda_1}$$
 then no epidemic occurs

Homogeneous models A general network model for SIS Scale-free network model for SIS

イロト イヨト イヨト イヨト

臣

Threshold phenomenon II

$$\begin{aligned} \zeta_i(t) &= \prod_{j:i-j} 1 - x_j(t-1)\beta \\ &\geqslant 1 - \beta \sum_{j:i-j} x_j(t-1) \\ &= 1 - \beta \sum_j A_{ij} x_j(t-1) \end{aligned}$$

Threshold phenomenon III

$$\begin{aligned} x_{i}(t) &= 1 - (1 - (1 - \gamma)x_{i}(t - 1))\zeta_{i}(t) \\ &\leqslant 1 - (1 - (1 - \gamma)x_{i}(t - 1))(1 - \beta \sum_{j} A_{ij}x_{j}(t - 1)) \\ &= 1 - (1 - (1 - \gamma)x_{i})(1 - \beta \sum_{j} A_{ij}x_{j}) \\ &= 1 - \left(1 - (1 - \gamma)x_{i} - \beta \sum_{j} A_{ij}x_{j} + (1 - \gamma)x_{i}\beta \sum_{j} A_{ij}x_{j}\right) \\ &= (1 - \gamma)x_{i} + \beta \sum_{j} A_{ij}x_{j} - (1 - \gamma)x_{i}\beta \sum_{j} A_{ij}x_{j} \\ &\leqslant (1 - \gamma)x_{i}(t - 1) + \beta \sum_{j} A_{ij}x_{j}(t - 1) \end{aligned}$$

Homogeneous models A general network model for SIS Scale-free network model for SIS

Threshold phenomenon IV

In matrix notation:

$$\mathbf{x}(t) \leqslant ((1-\gamma)\mathbf{I} + \beta \mathbf{A})\mathbf{x}(t-1)$$

Define $\boldsymbol{\mathsf{S}}=\beta\boldsymbol{\mathsf{A}}+(1-\gamma)\boldsymbol{\mathsf{I}},$ then

$$\mathbf{x}(t) \leqslant \mathbf{S}\mathbf{x}(t-1) \leqslant \mathbf{S}^2 \mathbf{x}(t-2) \leqslant ... \leqslant \mathbf{S}^t \mathbf{x}(0)$$

Assuming that $\mathbf{x}(0) = \sum_{r} a_r \mathbf{v}_r$, where \mathbf{v}_r are the eigenvectors of **S**

$$\mathbf{x}(t) \leqslant \mathbf{S}^t \sum_r a_r \mathbf{v}_r = \sum_r (\lambda_r)^t a_r \mathbf{v}_r$$

From linear algebra we know that $\lambda_1 > 0$ (matrix **S** is symmetric and real) and also $\lambda_1 > \lambda_2 > \ldots > \lambda_r$. For $t \to \infty$, the sum is dominated by the first eigenvalue and so

イロト イポト イヨト イヨト

Threshold phenomenon V

$$\mathbf{x}(t) \leqslant (\lambda_1)^t a_1 \mathbf{v}_1$$

If $\lambda_1 < 1$, then the epidemic must vanish (the other direction also holds, check [Chakrabarti et al., 2008]). Finally, the relation between the eigenvalues of $\mathbf{S} = (1 - \gamma)\mathbf{I} + \beta\mathbf{A}$ matrix and the ones of \mathbf{A} matrix is, for all r:

$$\lambda_r^S = 1 - \gamma + \beta \lambda_r^A$$

Homogeneous models A general network model for SIS Scale-free network model for SIS

・ロト ・回ト ・ヨト ・ヨト

Threshold phenomenon VI

So the final threshold (w.r.t. leading eigenvalue of A)

$$\begin{split} \lambda_1^S < 1 \\ \Longleftrightarrow \quad 1 - \gamma + \beta \lambda_1^A < 1 \\ \Leftrightarrow \quad 1 + \beta \lambda_1^A < 1 + \gamma \\ \Leftrightarrow \quad \beta \lambda_1^A < \gamma \\ \Leftrightarrow \quad \frac{\beta}{\gamma} < \frac{1}{\lambda_1^A} \end{split}$$

Homogeneous models A general network model for SIS Scale-free network model for SIS

Scale-free network model for SIS.

Recap: Homogeneous SIS model Equations of dynamics

$$\frac{ds}{dt} = \gamma x - \beta \langle k \rangle s x \qquad \qquad \frac{dx}{dt} = \beta \langle k \rangle s x - \gamma x$$

Solution

$$x(t) = x_0 \frac{(\beta \langle k \rangle - \gamma) e^{(\beta \langle k \rangle - \gamma)t}}{\beta \langle k \rangle - \gamma + \beta \langle k \rangle x_0 e^{(\beta \langle k \rangle - \gamma)t}}$$

Observations

- Same behavior as in the non-networked model
- Epidemic threshold at $\beta \langle k \rangle \gamma = 1$
 - Equivalent to $\frac{\beta}{\gamma} \leq \frac{1}{\langle k \rangle}$, same as SIR

< ロ > < 同 > < 三 > < 三 >

Homogeneous models A general network model for SIS Scale-free network model for SIS

<ロ> (四) (四) (三) (三) (三)

The scale-free model of epidemics for SIS I From [Pastor-Satorras and Vespignani, 2001]

Instead of assuming homogeneous mixing, have a different equation for all nodes of same degree k:

$$\frac{dx_k}{dt} = \beta k (1 - x_k) \Theta(\beta) - \gamma x_k$$

where

- ► (1 x_k) is the probability that a node of degree k is not infected
- $\Theta(\beta)$ is the probability that a neighbor is infected
- βkΘ(β) is the probability of contagion of a k-degree node from an infected neighbor

Homogeneous models A general network model for SIS Scale-free network model for SIS

<ロ> (四) (四) (三) (三) (三)

The scale-free model of epidemics for SIS II From [Pastor-Satorras and Vespignani, 2001]

Imposing stationarity $\left(\frac{dx_k}{dt} = 0\right)$, for all k), we obtain

$$x_k = \frac{k\beta\Theta(\beta)}{\gamma + k\beta\Theta(\beta)}$$

and so nodes with higher degree are more susceptible to being infected. W.l.o.g. may assume $\gamma = 1$.

The probability that any edge points to an *s*-degree node is proportional to sP(s), and by def. $\sum_{s} sP(s) = \langle k \rangle$. Therefore

$$\Theta(\beta) = \sum_{k} \frac{kP(k)x_{k}}{\sum_{s} sP(s)} = \frac{1}{\langle k \rangle} \sum_{k} kP(k)x_{k}$$

Homogeneous models A general network model for SIS Scale-free network model for SIS

イロト イヨト イヨト イヨト

The scale-free model of epidemics for SIS III From [Pastor-Satorras and Vespignani, 2001]

Plug in the expression for x_k to obtain

$$\Theta(\beta) = \frac{1}{\langle k \rangle} \sum_{k} k P(k) \frac{k \beta \Theta(\beta)}{1 + k \beta \Theta(\beta)}$$

A non-zero stationary prevalence $(x_k \neq 0)$ is obtained when both sides of previous eq., taken as funct. of Θ , cross in $0 < \Theta \leq 1$. This corresponds to

$$\frac{d}{d\Theta} \left(\frac{1}{\langle k \rangle} \sum_{k} k P(k) \frac{k \beta \Theta}{1 + k \beta \Theta} \right) \bigg|_{\Theta = 0} \ge 1$$

Homogeneous models A general network model for SIS Scale-free network model for SIS

イロン 不同 とくほど 不同 とう

The scale-free model of epidemics for SIS IV From [Pastor-Satorras and Vespignani, 2001]

The critical epidemic threshold β_c is the value β which yields equality above. This is given by

$$\frac{1}{\langle k \rangle} \sum_{k} k P(k) \beta_{c} k = \frac{\langle k^{2} \rangle}{\langle k \rangle} \beta_{c} = 1$$

Hence, $\beta = \frac{\langle k \rangle}{\langle k^2 \rangle}$ This implies that in scale-free networks, for which $\langle k^2 \rangle \rightarrow \infty$, we have $\beta_c = 0$.

イロト イヨト イヨト イヨト

The scale-free model of epidemics for SIS V From [Pastor-Satorras and Vespignani, 2001]

So, there is no epidemic threshold for (infinite) scale-free networks. In practice, the epidemic threshold in scale-free networks is going to be very small. As a consequence, viruses can spread and proliferate at any rate. However, this spreading rate is in general exponentially small.

(In the scale-free model of [Barabasi and Albert, 1999] we have $P(k) = 2m^2/k^3$ and so we obtain in this case (w.l.o.g. $\gamma = 1$)

$$\Theta(\beta) = rac{e^{-rac{1}{meta}}}{eta m} \qquad ext{and} \qquad x pprox 2e^{-rac{1}{meta}}$$
