**Task**: to provide an automated and efficient method to segment patients in groups with similar clinical profiles.

- $\textbf{ 0 Similar patients} \rightarrow \textbf{Similar cares}.$
- Pind recurrent comorbidities.
- S Assigning and planning resources: drugs and doctors.

ヨト イヨト

**Task**: to provide an automated and efficient method to segment patients in groups with similar clinical profiles.

- $\textbf{ 0 Similar patients} \rightarrow \textbf{Similar cares}.$
- Pind recurrent comorbidities.
- S Assigning and planning resources: drugs and doctors.

**Dataset**: all hospital admissions in Catalonia in 2016 (> 1 Mln records). Each row is a visit: up to 10 diagnostics in ICD-9 format.

In ICD code, to each disease is associated a number **Records**: list of patients with their diseases  $\rightarrow$  patient-disease matrix.

	Diseases		820	401	278	560
Patient 1	820, 401	Patient 1	1	1	0	0
Patient 2	401, 278,	Patient 2	0	1	1	0
Patient 3	560, 820, 278	Patient 3	1	0	1	1

In ICD code, to each disease is associated a number **Records**: list of patients with their diseases  $\rightarrow$  patient-disease matrix.

	Diseases		820	401	278	560
Patient 1	820, 401	Patient 1	1	1	0	0
Patient 2	401, 278,	Patient 2	0	1	1	0
Patient 3	560, 820, 278	Patient 3	1	0	1	1

**Objective**: cluster the rows of the patient-disease matrix. Sparse and high dimensional data.

**Standard methods**: *k-means, k-medioids, single linkage...* Distance-based: poor performances on high dimensional sparse data. Data is modeled as a mixture of independent Bernoulli variables

- $\bullet~$  Latent state  $\rightarrow~$  Medical status of a patient.
- Observed diseases depend on the patient status.
- Once in a status, diagnostics are independent.

#### Main advantages

- No distance required.
- Generative model  $\rightarrow$  clear interpretation.
- Clustering is performed via MAP assignment.

Retrieve from data estimates of the moments:

$$\begin{split} M_1 &= \sum_{i=1}^k \omega_i \, \mu_i \, \in \mathbb{R}^d \\ M_2 &= \sum_{i=1}^k \omega_i \, \mu_i \, \otimes \, \mu_i \, \in \mathbb{R}^{d \times d} \\ M_3 &= \sum_{i=1}^k \omega_i \, \mu_i \, \otimes \, \mu_i \, \otimes \, \mu_i \, \in \mathbb{R}^{d \times d \times d} \end{split}$$

Where  $M = [\mu_1, ..., \mu_k]$  and  $\omega = (\omega_1, ..., \omega_k)$  are the unknown centers of the mixture and the mixing weights.

Obtain mixture's parameters with tensor decomposition on the moments:

$$\mathcal{TD}(M_1, M_2, M_3) \rightarrow (M, \omega)$$

#### Main challenge:

To estimate the moments from data; we used an approximated approach.

We focus on two subsets of our dataset:

 Heart Failure Dataset: Patients having diagnostic 428 in the ICD-9 code (Heart Failure).

**2** "Tertiary" Dataset:

Patients with serious diseases to be treated in top hospitals.

Both contain around 20000 patient records.

## Heart Failure Dataset - Content of the clusters

Cluster 1: Hypertension, Tachycardia, Hypercholesterolemia, Diabetes mellitus, Obesity Cluster 2: Diabetes mellitus, Coronary atherosclerosis, Atherosclerosis aorta	Pulmo Disea Mit Hy	Cluster 3: Pulmonary hypertension, Diseases tricuspid valve, Mitral valve disorders, Hypertensive heart disease			Cluster 4: Hypertensive chronic, kidney disease, Chronic kidney disease, Acute kidney failure, Diabetes mellitus Cluster 5: Streptococcus infection, Vinary tract infection, Kidney failure, Hypertensive heart and chronic kidney disease			
Metabolic issues	Pre-exi							
Cluster ID:	1	2	3	4	5			
Size:	7290	2915	4408	2936	5533
