Load Balancing game

- There are *m* servers and *n* jobs. Job *i* has load p_i .
- The game has *n* players, corresponding to the *n* jobs.
- Each player has to decide the server that will process its job. $A_i = \{1, \dots, m\}$
- The response time of server *j* is proportional to its load

$$L_j(s) = \sum_{i|s_i=j} p_i.$$

 Each job wants to be assigned to the server that minimizes its response time:

$$c_i(s)=L_{s_i}(s).$$

11/36

イロト 不得 トイヨト イヨト 二日

Load Balancing game: PNE?

Consider the best response dynamic

- Start with an arbitrary state.
- A node (or several) chooses a best strategy, one that maximizes its own payoff, given the current choices of the others

Consider the best response dynamic

- Start with an arbitrary state.
- A node (or several) chooses a best strategy, one that maximizes its own payoff, given the current choices of the others
- How to prove that such a process converges to a PNE?

Consider the best response dynamic

- Start with an arbitrary state.
- A node (or several) chooses a best strategy, one that maximizes its own payoff, given the current choices of the others
- How to prove that such a process converges to a PNE?
- Seek for an adequate kind of potential function.

BR-inspired-algorithm analysis

• Order the servers with decreasing load (i.e., the decreasing response time):

$$L_1 \geq L_2 \geq \cdots \geq L_m.$$

• Player *i* moves from server *j* to *k* if $L_k + p_i < L_j$.

э

BR-inspired-algorithm analysis

• Order the servers with decreasing load (i.e., the decreasing response time):

$$L_1 \geq L_2 \geq \cdots \geq L_m.$$

- Player *i* moves from server *j* to *k* if $L_k + p_i < L_j$.
- Reorder the servers by decreasing load and repeat the process until no job can move.

BR-inspired-algorithm analysis

• Order the servers with decreasing load (i.e., the decreasing response time):

$$L_1 \geq L_2 \geq \cdots \geq L_m.$$

- Player *i* moves from server *j* to *k* if $L_k + p_i < L_j$.
- Reorder the servers by decreasing load and repeat the process until no job can move.
- Each step of the BR algorithm defines a sorted sequence of loads.

• Does the algorithm converge?

3

イロト イヨト イヨト

- Does the algorithm converge?
- There are a finite number of (possibly exponential) assignments of jobs to servers.

э

くロ と く 同 と く ヨ と 一

- Does the algorithm converge?
- There are a finite number of (possibly exponential) assignments of jobs to servers.
- At each step
 - Player *i* moves from server *j* to *k* if $L_k + p_i < L_j$.
 - Besides $L_j p_i < L_j$

イロト イポト イヨト ・ヨ

At least two terms of the new sorted load sequence decrease!

- So BR-inspired-algorithm terminates (although it can be rather slow).
- The load balancing game has a PNE.

Load Balancing game: Social cost

 The natural social cost is the total finish time i.e., the maximum of the server's loads

$$c(s) = \max_{j=1}^m L_j.$$

• How bad/good is a PNE?

< ロ > < 同 > < 回 > < 回 > < 回 > <

- Let *s* be an assignment with optimal cost.
- Is s a PNE?

э

- Let *s* be an assignment with optimal cost.
- Is s a PNE?
- not necessarily, no player in the worst server can improve, however other players can get a better benefit.

- Let *s* be an assignment with optimal cost.
- Is s a PNE?
- not necessarily, no player in the worst server can improve, however other players can get a better benefit.
- However, starting from an optimal solution the BR-inspired-algorithm terminates on a PNE with the same maximum load.

- Let s be an assignment with optimal cost.
- Is s a PNE?
- not necessarily, no player in the worst server can improve, however other players can get a better benefit.
- However, starting from an optimal solution the BR-inspired-algorithm terminates on a PNE with the same maximum load.
- Therefore, $PoS(\Gamma) = 1$.

Theorem

The max load of a Nash equilibrium s is within twice the max load of an optimum assignment, i.e.,.

$$C(s) \leq 2\min_{s'} C(s').$$

Which will give $PoA(\Gamma) \leq 2$.

Smoothness

A game is called (λ, μ) -smooth, for $\lambda > 0$ and $\mu \le 1$ if, for every pair of strategy profiles s and s', we have

$$\sum_{i\in N} c_i(s_{-i},s_i') \leq \lambda C(s') + \mu C(s).$$

Smoothness directly gives a bound for the PoA:

イロト イポト イヨト イヨト 三日

Smoothness

A game is called (λ, μ) -smooth, for $\lambda > 0$ and $\mu \le 1$ if, for every pair of strategy profiles s and s', we have

$$\sum_{i\in N} c_i(s_{-i},s_i') \leq \lambda C(s') + \mu C(s).$$

Smoothness directly gives a bound for the PoA:

Theorem

In a (λ, μ) -smooth game, the PoA for PNE is at most $\frac{\lambda}{1-\mu}$.

イロト イポト イヨト イヨト 三日

Proof of smoothness bound on PoA

Let s be the worst PNE and s^* be an optimum solution.

$$egin{aligned} \mathcal{C}(s) &= \sum_{i \in \mathcal{N}} c_i(s) \leq \sum_{i \in \mathcal{N}} c_i(s_{-i}, s_i^*) \ &\leq \lambda \mathcal{C}(s^*) + \mu \mathcal{C}(s) \end{aligned}$$

Substracting $\mu C(s)$ on both sides gives

$$(1-\mu)C(s) \leq \lambda C(s^*).$$

Theorem

Every congestion game with affine delay functions is (5/3, 1/3)-smooth. Thus, PoA $\leq 5/2$.

- 4 同 ト - 4 回 ト

Theorem

Every congestion game with affine delay functions is (5/3, 1/3)-smooth. Thus, PoA $\leq 5/2$.

The proof uses a technical lemma:

Lemma (Christodoulou, Koutsoupias, 2005)

For all integers y, z we have

$$y(z+1) \leq \frac{5}{3}y^2 + \frac{1}{3}z^2$$

A	G	-	VII	RI,	ĿН	В-!	UP	'L.

Recall that $d_e(x) = a_e x + b_e$. Note that using the Lemma

$$a_e y(z+1) + b_e y \le a_e(\frac{5}{3}y^2 + \frac{1}{3}z^2) + b_e y = \frac{5}{3}(a_e y^2 + b_e y) + \frac{1}{3}(a_e z^2 + b_e z).$$

イロト イポト イヨト イヨト 三日

Recall that $d_e(x) = a_e x + b_e$. Note that using the Lemma

$$\begin{aligned} a_e y(z+1) + b_e y &\leq a_e(\frac{5}{3}y^2 + \frac{1}{3}z^2) + b_e y = \frac{5}{3}(a_e y^2 + b_e y) + \frac{1}{3}(a_e z^2 + b_e z). \\ \text{Taking } y &= f_e(s^*) \text{ and } z = f_e(s) \text{ we get} \end{aligned}$$

$$(a_e(f_e(s)+1)+b_e)f_e(s^*) \leq \frac{5}{3}(a_ef_e(s^*)+b_e)f_e(s^*))+\frac{1}{3}(a_ef_e(s)+b_e)f_e(s)).$$

イロト イポト イヨト イヨト 三日

Recall that $d_e(x) = a_e x + b_e$. Note that using the Lemma

$$a_e y(z+1) + b_e y \le a_e(\frac{5}{3}y^2 + \frac{1}{3}z^2) + b_e y = \frac{5}{3}(a_e y^2 + b_e y) + \frac{1}{3}(a_e z^2 + b_e z).$$

Taking $y = f_e(s^*)$ and $z = f_e(s)$ we get

$$(a_e(f_e(s)+1)+b_e)f_e(s^*) \leq \frac{5}{3}(a_ef_e(s^*)+b_e)f_e(s^*))+\frac{1}{3}(a_ef_e(s)+b_e)f_e(s)).$$

Summing up all the inequalities

$$\sum_{e\in E} (a_e(f_e(s)+1)+b_e)f_e(s^*) \leq \frac{5}{3}C(s^*)+\frac{1}{3}C(s).$$

AGT-MIRI, FIB-UPC

Spring 2024

33 / 36

イロト 不得 トイヨト イヨト 三日

$$\sum_{e\in E} (a_e(f_e(s)+1)+b_e)f_e(s^*) \leq \frac{5}{3}C(s^*)+\frac{1}{3}C(s).$$

3

イロト イヨト イヨト

$$\sum_{e \in E} (a_e(f_e(s) + 1) + b_e) f_e(s^*) \leq \frac{5}{3}C(s^*) + \frac{1}{3}C(s).$$

But,

$$\sum_{i \in N} c_i(s_{-i}, s_i^*) \le \sum_{e \in E} (a_e(f_e(s) + 1) + b_e)f_e(s^*)$$

as there are at most $f_e(s^*)$ players that might move to resource r. Each of them by unilaterally deviating incur a delay of $(a_e(f_e(s) + 1) + b_e)$.

$$\sum_{e \in E} (a_e(f_e(s) + 1) + b_e) f_e(s^*) \leq \frac{5}{3}C(s^*) + \frac{1}{3}C(s).$$

But,

$$\sum_{i \in N} c_i(s_{-i}, s_i^*) \le \sum_{e \in E} (a_e(f_e(s) + 1) + b_e)f_e(s^*)$$

as there are at most $f_e(s^*)$ players that might move to resource r. Each of them by unilaterally deviating incur a delay of $(a_e(f_e(s) + 1) + b_e)$. This gives the (5/3, 1/3)-smoothness.
