Abstract. Though new technological trends and paradigms arise for developing complex software systems, systematic reuse continues to be an elusive goal. In this context, the adoption of Commercial Off-The-Shelf (COTS) technologies introduces many challenges that still have not been fully overcome, such as the lack of comprehensive mechanisms to record and manage the required information for supporting COTS components selection. In this paper we present a domain analysis approach for gathering the information needed to describe COTS market segments as required for effective COTS components selection. Due to the diversity of the information to capture, we propose different dimensions of interest for COTS components selection that are covered by different domain models. These models are articulated by means of a single framework based on a widespread software quality standard.

1 Introduction

Systematic reuse is based on the observation that quality and productivity can be significantly increased by building an infrastructure support. The engineering discipline concerned with building these optimal reusable assets is called *domain engineering* [1]. Domain engineering supports the notion of *domain*, a set of applications that use common concepts for describing requirements, problems, capabilities and solutions. Particularly, being part of domain engineering, *domain analysis* has been identified as a major factor in the success of software reusability [2]. Domain analysis refers to the process of identifying the basic elements of the domain, organizing an understanding of the relationships among these elements, and representing this understanding in a useful way by means of different types of domain models [3]. The different existing views on domain modelling (e.g., [1], [4], [5]) share the same goal: to facilitate quality software development by reusing the knowledge of the addressed domain.

Reuse is not a context-independent activity. The type of artifact to be reused impacts on the reuse models to be adopted and the reuse processes to be undertaken;

D.W. Embley, A. Olivé, and S. Ram (Eds.): ER 2006, LNCS 4215, pp. 354 – 370, 2006.

therefore, the reuse discipline has to evolve as new paradigms and artifacts emerge. In this context, we are interested in one particular case of those software artifacts, namely *Commercial Off-The-Shelf* (*COTS*) *components*. A COTS component is defined as "a product that is sold, leased or licensed to the general public, offered by a vendor trying to profit from it, supported and evolved by the vendor who retains the intellectual property rights, available in multiple identical copies and used without source code modification by a consumer" [6].

Successful COTS-based systems development requires an effective and efficient COTS selection process to deliver full potential to this technology. *COTS selection* is defined as the process of searching candidates and evaluating them with respect to the system requirements. Several COTS selection methods, processes and techniques have been formulated (see [7] for a recent survey). However, though these approaches have achieved significant results, they are mainly oriented to individual selection processes. Even in the cases in which a reuse infrastructure is suggested (e.g., OTSO, CARE, PECA), no real support or precise guidelines are offered.

To solve this problem, it seems feasible to use domain analysis for recording and structuring the informational dimensions required for selecting COTS components. This could be done by means of different domain models with the aim of supporting organizations that need continuously to carry out COTS selection processes in order to reuse their knowledge and information in a structured way (e.g., reusing criteria for COTS evaluation or reusing information of the organizational environment). However, as far as we know, COTS technology issues have not been explicitly addressed in the domain analysis discipline (although of course many concepts of domain analysis apply to this particular case).

The goal of this paper is to present a particular approach of domain analysis for supporting COTS components selection. This approach is part of our GOThIC (Goal-Oriented Taxonomy and reuse Infrastructure Construction) [8], a prescriptive goal-oriented method for building and maintaining a reliable reuse infrastructure in which COTS market segments are arranged to form a taxonomy whose nodes are decorated with domain models. In this sense, our domain analysis approach aims at producing several domain models for stating the most important aspects of a particular COTS segment in the COTS marketplace. Moreover, all these models are integrated and synchronized using a unifying framework and, widespread notations and standards.

The rest of the paper is organized as follows. Section 2 introduces the GOThIC method, the importance of domain analysis in its context and its feasibility. The informational dimensions for evaluating COTS components are identified in section 3. Section 4 discusses the most appropriate types of models to record these informational dimensions whilst section 5 explains how these models are integrated into a unified one. Section 6 illustrates our proposal with an example. Section 7 outlines the impact of domain analysis onto COTS components selection, and finally, conclusions are given in section 8.

2 The GOThIC Method

As a response to the need of organizing the knowledge of the COTS marketplace in a structured manner, we have formulated the GOThIC method [8]. Its ultimate goal is to

guide the construction and maintenance of goal-oriented taxonomies that describe the contents of the COTS marketplace. The method is articulated by means of several activities, such as the exploration of information sources, the identification of goals and their hierarchization. Among these activities, we also find domain analysis of the COTS marketplace segment being addressed by the taxonomy. This activity has the mission of producing an integrated domain model (representation of important aspects of a COTS segment) that serves as the basis to gain knowledge for identifying the correct goals and to build a reuse infrastructure with several kinds of reusable assets of interest for COTS selection processes.

From an operational point of view, the goal of the GOThIC method is to populate a knowledge base with data according to the UML [9] conceptual model sketched in Fig. 1. At the heart of this model lies the taxonomy composed of two types of nodes, market segments and categories, which are characterized by their goals. Market segments are the leaves of the taxonomy, whilst categories serve to group related market segments and/or subcategories (e.g., the category of communication infrastructure systems or financial packages). From a semantic point of view, market segments stand for the basic types of COTS components available in the marketplace, i.e. atomic entities covering a significant group of functionality such that their decomposition would yield to too fine-grained domains (e.g., the domain of anti-virus tools or spreadsheet applications). As a consequence, COTS components are associated with market segments and not with categories (although an indirect relationship exists, because market segments belong to categories). Components may cover more than one market segment. Taxonomy nodes have a generic domain model bound, which is built during the domain analysis activity. Their construction is a result of the integration of diverse models which are designed from the analysis of some information sources which are gathered, analyzed and prioritized according to several characteristics of the taxonomy construction project.

The taxonomy built with GOThIC may then be browsed during COTS selection to locate the market segment (or segments) of interest. Once found, the domain model bound may be used to obtain the appropriate criteria for selecting the most suitable component.

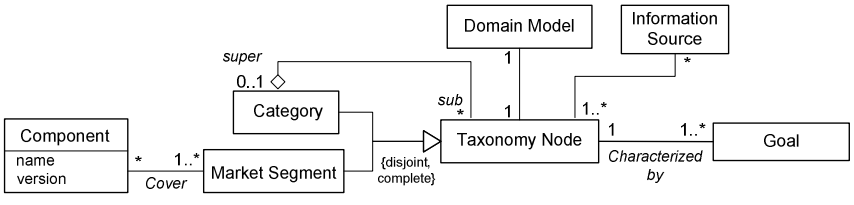

Fig. 1. Conceptual model for goal-oriented COTS taxonomies in the GOThIC method: overview

The feasibility of the GOThIC method depends on some premises:

- In general, it is mainly addressed to organizations that are carrying out subsequent COTS selection processes (e.g., a consultant company, a third-party software provider, an IT department of a big corporation, etc.). Therefore, they may find

valuable to have means to transfer knowledge from one experience to another (i.e. the return on investment for building a reuse infrastructure should be justified).

- It should be applied to a COTS segment that is of general interest. This means that a great deal of organizations needs to select COTS components from this segment. Some examples are: communication infrastructure, ERP systems, security-related systems, etc. In these contexts, the number of selection processes that take place will be high and then reusability of the models likely to occur.
- It should be addressed to COTS segment that offer components of coarse-grained granularity. This makes domain understanding more difficult, time-consuming and cumbersome and so domain analysis is helpful. Market segments such as CRM and ECM systems are typical examples, whilst time or currency converters are not.

3 Domain Analysis for Supporting COTS Selection: Dimensions

In the previous sections we have justified the convenience of having domain models for describing COTS marketplace segments. In this section, informational dimensions required for selecting COTS components are identified. Each dimension will be described by a model. To guide the identification of such dimensions, we analyze the different informational needs and facts of COTS selection processes that have been reported in the literature (e.g., [10, 11, 12]) as well as our own experiences in the field (e.g., [13, 14, 15, 16]).

Fundamental Concepts

In the COTS context the same concept may be denoted by different names in different products or even worse, the same term may denote different concepts in different products. Furthermore, currently, it is not usual to find places in the COTS marketplace where fundamental concepts are stated in a clear way, making difficult to use them, customize them and make them evolve as the marketplace does [17]. On the other hand, every single COTS segment defines lots of concepts that are used over and over, e.g., anti-virus tools have “viruses”, e-mail systems have “messages” and “folders”, etc. These concepts may be related in many ways, e.g. “messages” are “stored” inside “folders”. A poor knowledge of these fundamental concepts and semantic relationships may interfere with the efficiency and effectiveness of COTS selection processes. Therefore a model for representing all this information is needed. Its purpose is to settle the scope of a particular segment, to define its main concepts (both as a vocabulary and as a semantic model) and the relationships that facilitate the understanding of the domain as a whole. The resulting model can there be used as a reference framework for the segment. To build this model, information sources such as standards and textbooks are useful (see [8] for a set of suggested information sources). We recommend to choose one of the most trustable sources as starting point, then to synthesize the corresponding dimensions of the domain model, and last to calibrate this dimension with other informational sources.

Functionality

COTS components have their functionality already built-in, so it is a primary source of information for selecting them. Thus, instead of traditional requirements that

specify "must" and "should" needs, requirements for COTS-based systems articulate broad categories of needs and possible trade-offs. A domain model must cover this dimension, but a good balance is needed. On the one hand, the most representative functionalities of a particular segment should be included (e.g., virus repair, automatic resending of messages) and described up to a level of detail that enables efficient survey and evaluation of particular COTS components. On the other hand, if too much detail is given, several obstacles, remarkably growing size and evolvability of the COTS marketplace, are harder to overcome, since a lot of information would need to be updated continuously. Also, too much detail may commit the description of the functionality to the behaviour of particular components.

Quality of Service
Quality factors are likely to break the tie when several COTS candidates provide the required functionality; consequently the role of quality information becomes utterly important for driving COTS selection [18]. Therefore, a dimension for stating quality of service is required. The resulting model needs to offer a structured description of the COTS segment addressed, organizing the different quality factors hierarchically (e.g., Throughput and Response Time as subfactors of Time Efficiency) and should also include metrics for the quality factors. This model may serve as a framework in which particular COTS components may be evaluated and compared to user requirements during selection processes.

Non-technical Description
Despite the fact that the evaluation of candidate COTS components from a technical point of view (functionality and quality of service) is necessary, experiences in COTS selection show that non-technical information (i.e., information that does not refer directly to the intrinsic quality of software, but to its context, including economic, political and managerial issues; e.g., adequacy of the procedures imposed by the COTS with respect to procedures of the organization) must be taken into account and, in fact sometimes it is even more important than the technical information [19]. As a result, we need to record this information as part of the domain model. This new dimension must distinguish several concepts and focus on the commercial nature of COTS components, stating information about licensing issues, provider reputation, post-sale supporting services, etc. One should be aware that part of the information may be difficult to obtain (e.g., provider finance information) and the corresponding factor may not be included in the model for this reason.

Interoperability
The analysis of any COTS market segment shows that some relationships among components exist. We have analyzed the types of dependencies that may exist and we have concluded that a COTS component may need another for: enabling its functionality (e.g., document management tools need workflow technology to define life cycles); complementing its functionality with an additional feature, not originally intended to be part of its suitability (e.g., a web page edition tool can complement a web browser to facilitate web page edition); enhancing its quality attributes (e.g., resource utilization can be improved significantly using compression tools). However, in the context of COTS selection, interoperability has been dealt with in a case-by-case

basis. Furthermore, some of the COTS selection methods proposed so far just address single component selection, they do not even address the need to select a suite as final solution. Therefore we propose a new dimension to cover this need, otherwise COTS selection becomes not trustable. It is worth remarking that, since we are describing not a particular COTS component but a whole segment, interoperability issues must not be stated in much detail (e.g., data formats, API specificities, etc.); instead the model should include the needs and expectations that one type of component has on others in a very high-level way.

4 Domain Analysis for Supporting COTS Selection: Models

Taking into account the informational dimensions required by the COTS technology, in this section we discuss which are the most appropriated types of models for representing them. A first observation is that, due to their diversity, various types of models will be probably required.

In the domain analysis field, a variety of methods and techniques have been proposed as: FODA, DARE, ODM, DSSA and PLUS (see [20] and [21] for a survey) which use a diversity of different types of artefacts and mechanisms to record the knowledge that range from the traditional requirements models (namely models of data, behaviour, and function), as Data Flow diagrams [22], Entity-Relationship (ER) models [23], Object Oriented models [24], UML models [9] Scenarios [25], and Feature models [26], to UML metamodeling techniques and more elaborated UML extensions and stereotypes for dealing with domain structural elements, relations and domain variability [21, 27]. In practice, these proposals vary in their terms, notations, and emphases, but in general they are focused on designing product lines or product families for promoting reusability between software applications by means of an intended reuse plan [21, 27].

Furthermore, as far as we know, none of these approaches has examined in depth the special kind of relationships and information that the COTS technology requires. In this sense, we have studied whether the models proposed by the actual domain analysis practices could be suitable for recording all the COTS informational dimensions. We found that although some commonly used models could fit well enough for representing some dimensions, some other dimensions were still lacking of an adequated representation and analysis (see Table 1 for examples), for instance those relationships that enable interoperability among components, which could be partially fulfilled by establishing “Artifact Dependencies” (a special kind of variability in variability models for Software Product Lines design [21]), as well as the dimension related with stating non-technical information and quality of service (this last could also be partially addressed by test cases, but generally they are considered to be out of domain analysis).

For that reason, it is a fact that actual domain analysis approaches do not address in an optimal way all the fundamental informational dimensions required for assessing COTS components in terms of expressiveness and adequateness, structure, and compatibility. Hence, existent domain analysis strategies have to be somehow adapted and complemented to fully deal with the COTS technology characteristics [28, 29].

In the rest of this section, we propose a set of domain models for covering all the required COTS informational dimensions using widespread notations and standards. Table 1 summarizes our proposal and makes clear the gap for recording non-technical descriptions and interoperability with respect to other domain analysis approaches.

Table 1. Summary of domain analysis practices for representing COTS dimensions

COTS Dimension	Domain Analysis Practices	Our approach
Fundamental Concepts	ER Models, Feature Models, UML Diagrams, etc.	UML Class Diagrams + LEL
Functionality	Data Flow Diagrams, Scenarios, UML Diagrams, etc.	UML Use Case Diagrams + brief individual descriptions
Quality of Service	None	ISO/IEC 9126-1
Non-Technical Description	None	3 categories of non-technical factors
Interoperability	None	*i** SD Models

Fundamental Concepts

Two types of artifacts are adequate for representing fundamental concepts: conceptual data models or feature-oriented models to express the semantic meaning of the terms in the market segment together with their relationships; and a glossary to set up a vocabulary of the domain with information about synonymous and other lexical relationships. In particular, we have chosen UML class diagrams [9] for representing the semantic information due to its expressiveness and acceptance in the community. As for the glossary, the Language Extended Lexicon (LEL) [30] approach provides an adequate level of service since it allows to capture the meaning and fundamental relationships of the particular symbols (words or phrases) of the domain. The glossary includes at least the terms that appear in the rest of the models (e.g., the names of classes, attributes and associations of the UML class diagram). One could also think of the general concept of ontology [31] for capturing all the information needed.

Functionality

Any approach based on the concept of scenario seems a good option. As commented in section 3, the important point is to use the right level of detail. We propose the use of UML use case diagrams [9] for defining the functionalities of the COTS segment and a brief format of use cases [32] for describing them individually.

Quality of Service

Quality models [13] provide a measurable framework which precisely defines and consolidates the different views of quality (e.g. performance, reliability, integrity, etc.) which are required for COTS components evaluation. Among the different existing proposals, we have adopted the ISO/IEC 9126-1 standard [33] for several reasons, remarkably: it provides a two-level departing catalogue but at the same time it is highly customizable to each different COTS segment; there are some metrics already defined for this standard; and it is widespread. In the next section we give more details of this model.

Non-technical Description
Not only in the domain analysis context but in general, it is not usual to find models for representing non-technical information. Usually some categories are identified and for each of them, a list of non-technical factors identified. We have identified 3 high-level factors and 15 second-level subfactors referring to supplier information (e.g., financial information), cost information (e.g., licensing schemes) and other non-technical information about the product (e.g., history of versions). See [19] for more details.

Interoperability
Interoperability of COTS components is usually described by means of APIs or data formats. However, as already explained in section 3, we are interested in describing not particular COTS components but the general behavior of all the components belonging to a COTS segment, therefore we need more abstract descriptions. The combination of goal- and agent-oriented models provides a good response to our needs. Goals allow expressing needs and expectations in a high-level way, whilst agents are an appropriate way to model COTS segments. Then, one COTS segment may state that depends on another to attain a goal. We have chosen *i** Strategic Dependency (SD) models [34], adapting its semantic to represent COTS segments and their dependencies. See [35] for details.

5 A Unifying Model for COTS Domain Analysis

The models proposed in section 4 cover the informational dimensions that were identified in section 3. However, the primary goal of COTS segments domain analysis is to characterize COTS components for their evaluation and selection, so it is clear that having these dimensions structured in separate models hampers domain understanding and model management. For this reason, we need a unifying model which facilitates this goal. Thus, from the dimension models given, quality models seem the most appropriate type of artefact. Therefore, if we succeed in putting all the models in an ISO/IEC 9126-1 quality model we will have our goal attained.

5.1 The ISO/IEC 9126 Quality Standard

The ISO/IEC 9126-1 software quality standard proposes quality models as the artifacts that keep track of the quality factors that are of interest in a particular context. The ISO/IEC 9126-1 standard fixes 6 top level characteristics: functionality, reliability, usability, efficiency, maintainability and portability. It also fixes their further refinement into 27 subcharacteristics but does not elaborate the quality model below this level, making thus the model flexible. To carry out this refinement, subcharacteristics are, in turn, decomposed into attributes, which represent the properties that the software products belonging to the domain of interest exhibit. Intermediate hierarchies of subcharacteristics and attributes may appear making thus the model highly structured. Metrics are bound to attributes. The standard is highly customizable to different purposes and domains; e.g., in our previous work [19], we

have created an extension for the particular case of quality of COTS components, and new subcharacteristics and attributes have been introduced.

5.2 Integrating All the COTS Domain Models into the ISO/IEC 9126-1

In this subsection we aim at integrating the domain models obtained so far, even considering their different nature, into an ISO/IEC 9126-1 quality model. Fig. 2 shows an overview of our proposed framework.

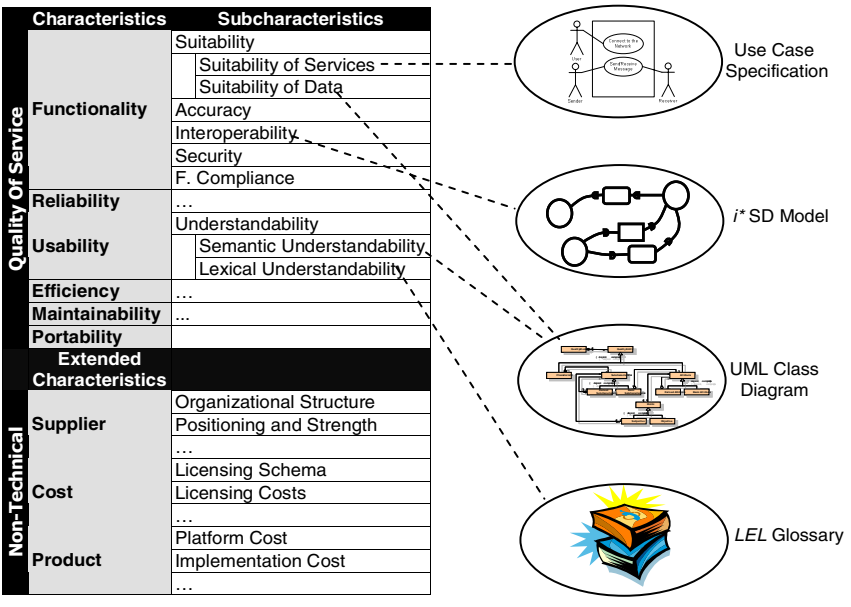

Fig. 2. An overview of the ISO/IEC 9126-1-based quality model for COTS segments

Functionality
Regardless of having the same name, the functionality of a COTS segment does not correspond with the ISO/IEC *Functionality* characteristic. Instead, it corresponds to the *Suitability* concept that is a subcharacteristic of *Functionality*. However, since functionality focuses on the services provided but not the data managed, we create a new subcharacteristic *Suitability of Services* that contains the UML Use Case diagram and the individual use case descriptions.

Fundamental Concepts
The UML class diagram is related to two ISO/IEC subcharacteristics. On the one hand, as the case before, *Suitability*, because some of the classes (and their attributes) and relationships are defining part of the suitability of the COTS segment. On the other hand, *Understandability*, which is a subcharacteristic of *Usability*, because having a UML class diagram provides a reference framework that allows testing how much a particular COTS component adheres to it. For the same reason, also the LEL

glossary supports *Understandability*. Therefore, we create 3 new subcharacteristics; *Suitability of Data*, belonging to *Suitability*, contains the class diagram; *Semantic Understandability* and *Lexical Understandability*, belonging to *Understandability*. The first one also contains the class diagram and the second one the glossary.

Non-technical Description
For arranging non-technical factors proposed in [19] in an ISO-9126-1-form, we define the 3 high-level ones as characteristics and the other 15 as subcharacteristics.

Interoperability
Interoperability is also a subcharacteristic of *Suitability* and in this case, we just consider the *i** SD model as the description of *Interoperability*.

5.3 Transforming the Models into the ISO/IEC 9126-1 Framework

Although we have achieved our primary goal, namely integrating all the dimension models under the same umbrella, there is still a question left that may be considered as a drawback when using the domain model for COTS components evaluation purposes: the fundamental concepts, functionality and interoperability models are expressed with their own formalisms which are not straightforward to evaluate. In this subsection we deal with this problem by providing rules that map the constructs in these models into ISO/IEC 9126-1 quality factors. Furthermore, we state how their metrics are defined. These rules are defined in such a way that they could generate the new, final model automatically from the former models.

Functionality
For each use case UC appearing in the Use Case diagram, a quality attribute UC belonging to the *Suitability of Services* subcharacteristic is created. The individual use case specifications are part of the description of these quality attributes.

For each obtained quality attribute, an ordinal metric which can take three values, Satisfactory, Acceptable and Poor, is created. These values express how a particular COTS component covers the service represented by the use case.

Fundamental Concepts
For each class or association C appearing in the class diagram that represents a concept provided by the COTS components in the segment, a quality attribute C belonging to the *Suitability of Data* subcharacteristic is created. The elements of the class diagram are part of the description of these quality attributes.

For each obtained quality attribute, an ordinal metric which can take three values, Satisfactory, Acceptable and Poor, is created. These values express how a particular COTS component provides the data represented by the class or association. These values will be obtained during evaluation by using different criteria (e.g., whether all the attributes are provided, whether the instances are permanent or not, etc.).

Each term of the glossary is included as part of the description of the quality attribute(s) it is related to. The same happens with the elements of the class diagram that were not tackled in the previous step. Last, two numerical metrics are bound to the *Semantic Understandability* and *Lexical Understandability* attributes. The values

of these metrics will count the number of semantic and lexical discrepancies of a particular COTS component with respect to the reference models.

Interoperability
For each agent A appearing the *i** SD model, except the agent S that represents the COTS segment we are modeling, a subcharacteristic A belonging to *Interoperability* is created.

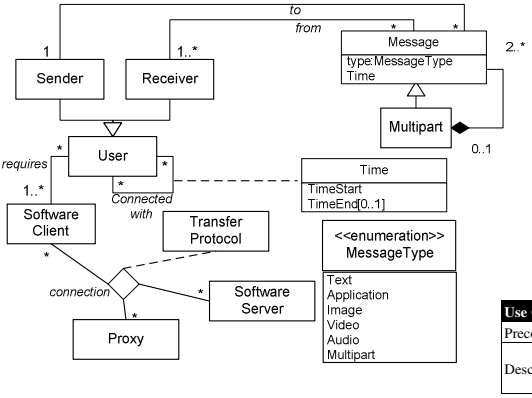
For each dependency G among S and A, an attribute G is created. For each obtained quality attribute, we create an ordinal metric whose values depend on the type of the corresponding dependency: if goal, values are Attained and Not Attained; if resource, Provided and Not Provided; if task, Executed or Failed; if softgoal, Satisfactory, Acceptable and Poor.

Once these rules are applied, evaluation of COTS component may be done in a more uniform and comfortable way. But of course, the original models should be preserved since they are easier to understand and evolve.

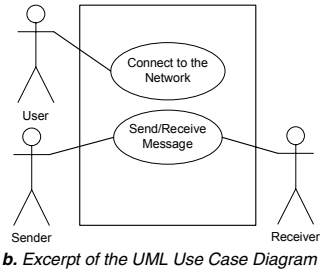
6 Example: The Real-Time Synchronous Communication Domain

For illustrating our proposal, we present some excerpts of the domain model obtained for the Real-Time Synchronous Communication (RTSC) market segment. This segment embraces the various tools and technologies used to enable communication and collaboration among people in a "same time-different place" mode.

Fundamental Concepts
Part of the UML class diagram is presented in Fig. 3a. Several key concepts are stated as classes. These concepts are of different nature, e.g. human roles (e.g. *Sender* and *Receiver*), artefacts of any kind (either physical or informational, e.g. *Message*), software and hardware domain-specific components (e.g. *Software Client, Software Server* and *Proxy*), etc. Inside these classes, we identify attributes but just those that



a. Excerpt of the UML Class Diagram



b. Excerpt of the UML Use Case Diagram

Use Case:	Send/Receive Message
Precondition	Sender and Receiver are connected with each other.
Description	The Sender composes a message of any kind and delivers it to the Receiver. The Receiver is notified and then reads the message

c. Excerpt of an Individual Use Case Specification

Fig. 3. Excerpt of some domain models constructed for the RTSC case

play a crucial part in the domain, e.g. *Message* that can be of different types. Domain relationships are also of different kinds. Thus, we can see a high-level relationship among the human roles *Sender* and *Receiver* which are generalized into a *User* class. On the other hand, associations may be of very different nature. For instance, we have permanent or at least very stable relationships (e.g., among *User* and *Software Client*) while others are highly dynamic (real-time connections that are created and destroyed dynamically). OCL restrictions may be used to decorate the model appropriately.

Functionality

As stated in section 3, the use case model for functionality focuses on the most characteristic services offered by packages in this domain. Fig. 3b shows some for the RTSC domain, namely *Connect to the Network* and *Send/Receive Message*. Others such as *Send Video Message* or *Connecting Multiuser Session* are not included either because they are not considered general enough but specific of a few COTS components, or because they are considered as secondary. In addition, we can also check that the individual use case specification of *Send/Receive Message* presented in Fig 3c follows the given recommendation of being very abridged.

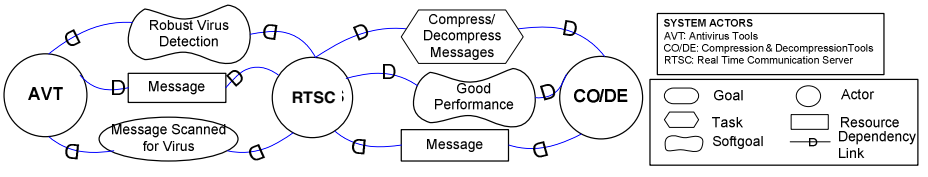


Fig. 4. Some dependencies among RTSC Tools and other types of tools

Interoperability

As it is the usual case in COTS segments that offer a lot of functionality, we may identify several relationships with other types of COTS domains. In Fig. 4 we introduce as example two COTS segments related with RTSC, AntiVirus Tools (AVT) and Compression/Decompression Tools (CO/DE), all of them modelled as *i** actors. Among their relationships, we find: a RTSC component relies on an AVT component for detecting viruses (goal dependency, since the AVT decides the best way to do it) and requires this detection to be robust (softgoal dependency, because the concept of "robust" detection is matter of negotiation); a RTSC component depends on a CO/DE one to compress/decompress messages automatically (task dependency, because the RTSC states when and how these automatic activities are done); a RTSC component may improve its performance using a CO/DE component (softgoal dependency, because the concept of "good" performance is matter of negotiation); and both related components need the message to work with from a RTSC component (resource dependency, because it is an informational entity).

Quality of Service

In table 2 we decompose a bit the *Understandability* subcharacteristic with the *Adherence to Best Practices* and *Supported Interface Languages* attributes. We include specific metrics that help to evaluate and compare user requirements. The first

metric illustrate the subjective case, whilst the second one illustrates a metric that is both objective and structured (set of values). The description included in the table is in fact part of the glossary but appears for legibility purposes.

Non-technical Description
Table 3 shows an excerpt of the refinement of a non-technical factor of a product, its stability. Note the similarity compared to quality of service description, which facilitates further integration. It should be mentioned that non-technical factors are very similar among different COTS segments.

Table 2. Excerpt of the quality model for the RTSC case

Quality factor	Metric	Description
3 Usability		ISO/IEC 9126-1 Characteristic
1 Understandability		ISO/IEC 9126-1 Subcharacteristic
3 Interface Understandability		Effort to recognizing the logical concepts and its applicability by means of interfaces.
1 Adherence to Best Practices	ADP: 4valueOrder[Ordinal] 4valueOrder = (Optimal, Good, Fair, Poor)	How well events and elements of the interface comply with user interface best practices.
2 Supported Interface Languages	SIL: Languages = Set(Labels[Nominal]) Labels = (Spanish, Catalan, English, …)	Languages supported by the interface.

Table 3. Excerpt of a non-technical factor decomposition for the RTSC case

Non-technical factor	Metric	Description
3 Product		Non-technical characteristics of a COTS product that may influence COTS selection
1 Stability		
1 Time of Product in the Market	TPM: Time[Ratio] Time = Float	Number of years the product has been in the marketplace
2 Versions Currently in the Market	VCM: List(Version[Nominal]) Version = String	Versions currently available in the marketplace
3 In-house Product	IP: Own[Nominal] Own = (Yes, Not)	Whether the product is in-house or acquired from a third party

Table 4 shows the integration of the presented excerpts in the unifying model using the mapping rules introduced in the section 5.3.

7 Domain Analysis-Based COTS Selection

Our domain analysis strategy has been integrated into the GOThIC method by considering that the ISO/IEC 9126-1-based quality model for COTS segments introduced in Fig. 2 is in fact the Domain Model that appears in Fig. 1. As stated in section 2, a GOThIC taxonomy is used to locate the taxonomy node that fulfils the

needs of the user in charge of the selection process. Once located, its domain model may be used to guide the rest of the selection process by refining this model with more specific requirements. The factors in the ISO/IEC 9126-1-based quality model help to elicit and negotiate the requirements, making easier the identification of mismatches among components characteristics and the requirements. Moreover, those factors corresponding to the stated requirements are used to evaluate the capabilities of the candidate components in a uniform way, using the metrics defined in the model. For doing so, we can proceed manually, or use tool support ranging from a simple spreadsheet to a more sophisticated tool, e.g. our DesCOTS system [36].

8 Conclusions

We have detailed the domain analysis approach for building a reuse infrastructure for supporting COTS selection processes enclosed in our GOThIC method. This approach is based on the application of domain analysis principles for recording and representing all the required information for evaluating COTS. Our proposal relies on several industrial experiences that have been undertaken under action-research premises, complemented with literature survey and grounded theory.

These industrial experiences have been carried out in the field of Workflow Systems [14], Requirements Engineering Tools [15], Telephony Systems [16] and some sub-categories of Enterprise Applications (with emphasis with those related to Content Management). Industrial experiences have been complemented with academic ones (e.g. Real-Time Synchronous Communication and Message-based Communication Systems) to analyse in more depth some particular aspects.

Concerning domain analysis, we have concluded that existing approaches were not oriented to support reuse in the COTS framework, consequently the need of mechanisms to analyze and create a reuse infrastructure for COTS domains still remained. In particular, it is required to represent interoperability among COTS components and to analyze non-technical factors that may influence the selection, as well as the need of putting more emphasis to software quality issues.

With respect to COTS selection:

- We have put the emphasis on reuse, making a concrete proposal based on the domain analysis technique which allows transferring knowledge from one experience to another.
- We have explicitly identified the informational dimensions required for the effective and efficient selection of COTS components.
- We have offered guidance for representing these informational dimensions using appropriate types of domain models.
- Using some mapping rules, we have integrated all these models into a single one, based on a well-known standard, highly oriented to support the evaluation of the candidate components.
- Given this representation, we may use some existing tool-support to conduct the evaluation of candidates in the framework of the ISO/IEC 9126-1 standard.
- Domain analysis not only impacts positively on reuse, but also ameliorates some well-known obstacles for COTS selections success [8]. Remarkably, using domain analysis principles we avoid those semantic and syntactic discrepancies that are common in the COTS marketplace.
