Recursion

• A subprogram is recursive when it contains a call to itself.

• Recursion can substitute iteration in program design:
  – Generally, recursive solutions are simpler than (or as simple as) iterative solutions.
  – There are some problems in which one solution is much simpler than the other.
  – Generally, recursive solutions are slightly less efficient than the iterative ones (if the compiler does not try to optimize the recursive calls).
  – There are natural recursive solutions that can be extremely inefficient. Be careful!

Factorial

```c++
// Pre: n >= 0
// Returns n!
int factorial(int n) { // iterative solution
    int f = 1;
    int i = 0;
    // Invariant: f = i! and i <= n
    while (i < n) {
        i = i + 1;
        f = f*i;
    }
    return f;
}
```

• Definition of factorial:

\[ n! = n \cdot (n - 1) \cdot (n - 2) \cdots 2 \cdot 1 \]

• Recursive definition:

\[ n! = \begin{cases} n \cdot (n - 1)!, & n > 0 \\ 1, & n = 0 \end{cases} \]
Factorial

// Pre: n >= 0
// Returns n!

int factorial(int n) { // recursive solution
    if (n == 0) return 1;
    else return n*factorial(n - 1);
}

Recursive design

In the design of a recursive program, we usually follow a sequence of steps:

1. Identify the basic cases (those in which the subprogram can solve the problem directly without recurring to recursive calls) and determine how they are solved.

   For example, in the case of factorial, the only basic case used in the function is n=0. Similarly, we could have considered a more general basic case (e.g., n ≤ 1). In both cases, the function should return 1.

   • For example, it is not clear whether the following function terminates:

   int Collatz(int n) { // recursive solution
       if (n == 1) return 0;
       else if (n%2 == 0) return 1 + Collatz(n/2);
       else return 1 + Collatz(3*n + 1);
   }

   • The reason is that 3*n+1 is not closer to 1 than n

2. Determine how to resolve the non-basic cases in terms of the basic cases, which we assume we can already solve.

   In the case of a factorial, we know that the factorial of a number n greater than zero is n*factorial(n-1).

3. Make sure that the parameters of the call move closer to the basic cases at each recursive call. This should guarantee a finite sequence of recursive calls that always terminates.

   In the case of a factorial, n-1 is closer to 0 than n. Therefore, we can guarantee that this function terminates.
Recursion: behind the scenes

- Each time a function is called, a new instance of the function is created. Each time a function "returns", its instance is destroyed.

- The creation of a new instance only requires the allocation of memory space for data (parameters and local variables).

- The instances of a function are destroyed in reverse order to their creation, i.e. the first instance to be created will be the last to be destroyed.

Write the binary representation

Design a procedure that, given a number $n$, writes its binary representation.

```
// Pre: $n > 0$
// Post: the binary representation of $n$ has been written.
void base2(int n) {

  // Basic case (n=1)  write "1"

  // General case (n>1) write n/2 and then write n%2
```
Write the binary representation

```cpp
// Pre: n > 0
// Post: the binary representation of n has been written.
void base2(int n) {
    if (n == 1) cout << n;
    else {
        base2(n/2);
        cout << n%2;
    }
}
```

The procedure always terminates since n/2 is closer to 1 than n. Note that n/2 is never 0 when n > 1. Therefore, the case n = 1 will always be found at the end of the sequence call.

The Fibonacci numbers are:

```
<table>
<thead>
<tr>
<th>order</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
</tr>
</thead>
<tbody>
<tr>
<td>fib</td>
<td>1</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>5</td>
<td>8</td>
<td>13</td>
<td>21</td>
<td>34</td>
<td>55</td>
</tr>
</tbody>
</table>
```

- In general, except for n = 0 and n = 1, the Fibonacci number of order n is equal to the sum of the two previous numbers.

Fibonacci numbers

```cpp
// Pre: n >= 0
// Returns the Fibonacci number of order n.
int fib(int n) {
    // Recursive solution
    if (n <= 1) return 1;
    else return fib(n - 2) + fib(n - 1);
}
```

- Design a function that, given a number n, returns the Fibonacci number of order n.

The function always terminates since the parameters of the recursive call (n-2 and n-1) are closer to 0 and 1 than n.
Fibonacci numbers

The tree of calls for fib(5) would be:

```
  fib(5)
    fib(4)
      fib(3)
        fib(2)
          fib(1)
            fib(0)
```

• When fib(5) is calculated:
  – fib(5) is called once
  – fib(4) is called once
  – fib(3) is called twice
  – fib(2) is called 3 times
  – fib(1) is called 5 times
  – fib(0) is called 3 times

• When fib(n) is calculated, how many times will fib(1) and fib(0) be called?

• Example: fib(50) calls fib(1) and fib(0) about $2.4 \cdot 10^{10}$ times

```
// Pre: n >= 0
// Returns the Fibonacci number of order n.
int fib(int n) { // iterative solution
    int i = 1;
    int f_i = 1;
    int f_i1 = 1;
    // Inv: f_i is the Fibonacci number of order i.
    //      f_i1 is the Fibonacci number of order i-1.
    while (i < n) {
        int f = f_i + f_i1;
        f_i1 = f_i;
        f_i = f;
        i = i + 1;
    }
    return f_i;
}
```

• With the iterative solution, if we calculate fib(5), we have that:
  – fib(5) is calculated once
  – fib(4) is calculated once
  – fib(3) is calculated once
  – fib(2) is calculated once
  – fib(1) is calculated once
  – fib(0) is calculated once
• We want to read a text represented as a sequence of characters that ends with ‘.’

• We want to calculate the number of occurrences of the letter ‘a’

• We can assume that the text always has at least one character (the last ‘.’)

• Example: the text

Programming in C++ is amazingly easy !.

has 4 a’s

// Input: a sequence of characters that ends with ‘.’
// Returns the number of times ‘a’ appears in the sequence (and the sequence has been read)

int count_a() {
    char c;
    cin >> c;
    if (c == '.') return 0;
    else if (c == 'a') return 1 + count_a();
    else return count_a();
}

Even though it has no parameters, we can see that the function terminates if we consider that the input is an implicit parameter. At every recursive call, a new char is read. Therefore, each call moves closer to reading the final dot.

• The puzzle was invented by the French mathematician Édouard Lucas in 1883. There is a legend about an Indian temple that contains a large room with three time-worn posts in it, surrounded by 64 golden disks. To fulfil an ancient prophecy, Brahmin priests have been moving these disks, in accordance with the rules of the puzzle, since that time. The puzzle is therefore also known as the Tower of Brahma puzzle. According to the legend, when the last move in the puzzle is completed, the world will end. It is not clear whether Lucas invented this legend or was inspired by it.

• Rules of the puzzle:
  – A complete tower of disks must be moved from one post to another.
  – Only one disk can be moved at a time.
  – No disk can be placed on top of a smaller disk.

Not allowed!
• What rules determine the next move?
• How many moves do we need?
• There is no trivial iterative solution.

**Inductive reasoning:** assume that we know how to solve Hanoi for \( n-1 \) disks

- Hanoi(\( n-1 \)) from left to middle (safe: the largest disk is always at the bottom)
- Move the largest disk from the left to the right
- Hanoi(\( n-1 \)) from the middle to the right (safe: the largest disk is always at the bottom)
void Hanoi(int n, char from, char to, char aux) {
    if (n > 0) {
        Hanoi(n - 1, from, aux, to);
        cout << "Move disk from " << from
             << " to " << to << " endl;"
        Hanoi(n - 1, aux, to, from);
    }
}

int main() {
    int Ndisks;
    cin >> Ndisks;
    Hanoi(Ndisks, 'L', 'R', 'M');
}
Tower of Hanoi

- How many moves do we need for n disks?

\[ \text{Moves}(n) = 1 + 2 \times \text{Moves}(n-1) \]

<table>
<thead>
<tr>
<th>n</th>
<th>Moves(n)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>7</td>
</tr>
<tr>
<td>4</td>
<td>15</td>
</tr>
<tr>
<td>5</td>
<td>31</td>
</tr>
<tr>
<td>6</td>
<td>63</td>
</tr>
<tr>
<td>n</td>
<td>(2^{n-1})</td>
</tr>
</tbody>
</table>

Digital root

- Let us assume that we can move one disk every second.

- How long would it take to move n disks?

<table>
<thead>
<tr>
<th>n</th>
<th>time</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1s</td>
</tr>
<tr>
<td>5</td>
<td>31s</td>
</tr>
<tr>
<td>10</td>
<td>17m 3s</td>
</tr>
<tr>
<td>15</td>
<td>9h 6m 7s</td>
</tr>
<tr>
<td>20</td>
<td>12d 3h 16m 15s</td>
</tr>
<tr>
<td>25</td>
<td>1y 23d 8h 40m 31s</td>
</tr>
<tr>
<td>30</td>
<td>&gt; 34y</td>
</tr>
<tr>
<td>40</td>
<td>&gt; 34,000y</td>
</tr>
<tr>
<td>50</td>
<td>&gt; 35,000,000y</td>
</tr>
<tr>
<td>60</td>
<td>&gt; 36,000,000,000y</td>
</tr>
</tbody>
</table>

- The digital root (or the repeated digital sum) of a number is the number obtained by adding all the digits, then adding the digits of that number, and then continuing until a single-digit number is reached.

- For example, the digital root of 65536 is 7, because \(6 + 5 + 5 + 3 + 6 = 25\) and \(2 + 5 = 7\).
Digital root

- **Basic case**: $n$ can be represented as a single-digit number $\rightarrow$ return $n$

- **General case**: $n$ has more than one digit
  - Calculate the sum of the digits
  - Calculate the digital root of the sum

```cpp
// Assume we have a function (to be defined)
// that calculates the sum of the digits of a number

// Pre: $n \geq 0$
// Returns the sum of the digits of $n$
// (represented in base 10)
int sumdigits(int n);

// Pre: $n \geq 0$
// Returns the digital root of $n$
int digital_root(int n) {
    if (n < 10) return n;
    else return digital_root(sumdigits(n));
}
```

Write a number $n$ in base $b$

- Design a program that writes a number $n$ in base $b$.

- Examples:

  1024 is 10000000000 in base 2
  1101221 in base 3
  2662 in base 7
  1024 in base 10

- **Basic case**: $n = 0$ $\rightarrow$ do not write anything (avoid writing numbers with a leading 0). Treat the zero as a special case outside the function.

- **General case**: $n > 0$
  - Write the leading digits of the number ($n/b$)
  - Write the last digit of the number ($n\%b$)
Write a number \( n \) in base \( b \)

// Writes the representation of \( n \) in base \( b \) (\( n \geq 0, 2 \leq b \leq 10 \))
// No digits are written when \( n = 0 \).

```cpp
void write_base(int n, int b) {
    if (n > 0) {
        write_base(n/b, b);
        cout << n%b;
    }
}
```

// Input: read two numbers, \( n \) and \( b \), with \( n \geq 0 \) and \( 2 \leq b \leq 10 \)
// Output: write the representation of \( n \) in base \( b \).

```cpp
int main() {
    int n, b;
    cin >> n >> b;
    if (n == 0) cout << "0";
    else write_base(n, b);
    cout << endl;
}
```
