$$(\forall x. (P(f(x)) \Rightarrow x < 0)) \Rightarrow (P(f(42)) \Rightarrow 42 < 0)$$

it can deduce the query to be unsatisfiable using only ground reasoning.

How do we figure the correct instantiation out?

Triggers (an idea borrowed from Simplify)

- triggers are subterms present in the quantified formula, which can be automatically generated, or come with the input
- we only consider instances, for which the trigger after substitution is present somewhere in the model returned by the SAT solver

Triggers (an idea borrowed from Simplify)

- triggers are subterms present in the quantified formula, which can be automatically generated, or come with the input
- we only consider instances, for which the trigger after substitution is present somewhere in the model returned by the SAT solver
- for example if we have a formula

$$\psi \equiv \forall x, y. F(x, y) \Rightarrow g(x) = h(y)$$

for which $F(x, y)$ is a trigger and the current model returned by the SAT solver is:

$$\psi \wedge F(1, c) \wedge g(7) = h(c)$$

we only consider instance where $x \rightarrow 1, y \rightarrow c$, because $F(1, c)$ is present in the monome.

Problem

E-matching

Simplify's
matcher

Subtrigger
matcher

S-trees

The matcher

Flat matcher

Implementation

Wrapping up

- this picture with the triggers is slightly more involved, because we are interested in the trigger being present in the monome *up to equivalence*
- for example trigger $F(x, c)$ does not syntactically match in $F(1, d) \wedge c = d$, but we would like it to

Problem
E-matching

Simplify's
matcher

Subtrigger
matcher

S-trees
The matcher

Flat matcher

Implementation

Wrapping up

Input

- a finite set \mathcal{A} of *active* ground terms,
- a relation $\cong_g \subseteq \mathcal{A} \times \mathcal{A}$,
- a finite set of non-variable, non-constant *triggers* p_1, \dots, p_n .

Definitions

- let $\cong \subseteq \mathcal{T} \times \mathcal{T}$ be the smallest congruence relation containing \cong_g ,
- let $\text{root}(t)$ denote a canonical representative of equivalence class containing t .

The solution to the E-matching problem is the set:

$$\mathcal{T} = \left\{ \sigma \mid \begin{array}{l} \exists t_1, \dots, t_n \in \mathcal{A}. \sigma(p_1) \cong t_1 \wedge \dots \wedge \sigma(p_n) \cong t_n, \\ \forall x \in \mathcal{V}. \sigma(x) = \text{root}(\sigma(x)) \end{array} \right\}$$

Problem

E-matching

Simplify's
matcher

Subtrigger
matcher

S-trees

The matcher

Flat matcher

Implementation

Wrapping up

- the problem of checking if $T \neq \emptyset$ for a fixed \mathcal{A} and \cong_g is NP-hard
- there can be exponential number of instances of a trigger
- the practical problem is, however, that there are often millions of matching problems to solve during solving of a single SMT query

Subtrigger
matcher

S-trees

The matcher

Flat matcher

Implementation

Wrapping up

- even this algorithm was taking up a lot of time, mainly because the loop over all terms with given head is performed for each trigger
- but it seems that a lot (most?) of the triggers are even simpler – they have variables only at depth one: $f(X, Y)$, $f(c, X)$, $f(X, c, Y, g(g(d)), Z)$
- this means one can put all such *flat* triggers with head f in an indexing tree and match them all at once during one loop over terms with head f
